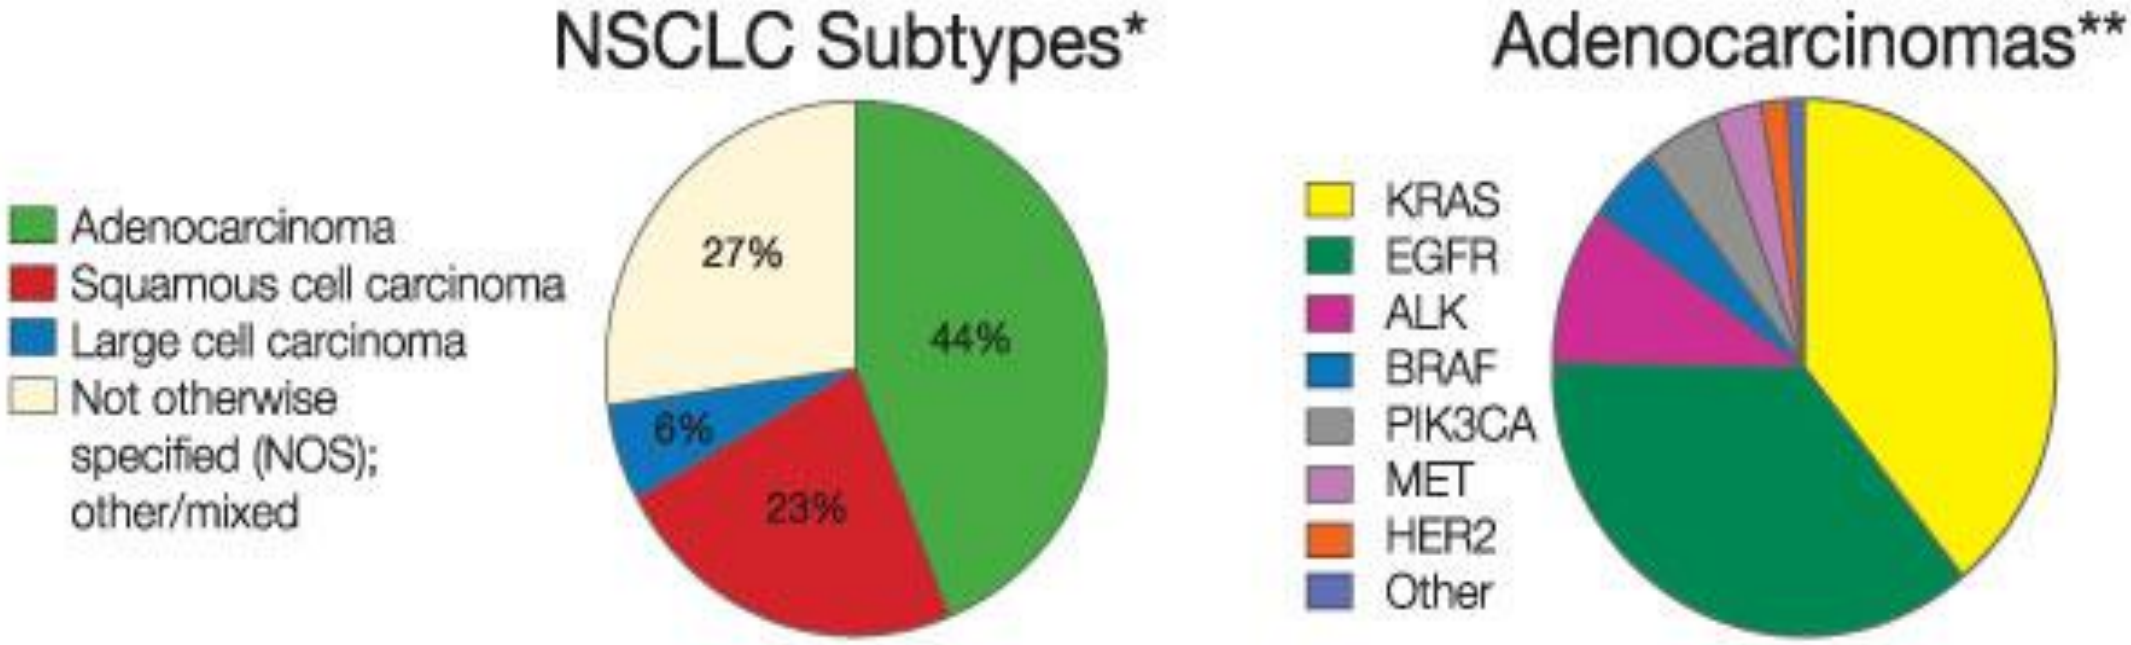
Introduction

- Recently, molecular-targeted therapies have been developed for cancer treatment, especially for lung cancer treatment.
- Non-small cell lung cancer (NSCLC） patients with epidermal growth factor receptor (EGFR) gene mutations have shown a dramatic response to EGFR tyrosine kinase inhibitors (EGFR-TKI) such as gefitinib and erlotinib.
- EML4-ALK fusion protein is present in approximately 5% of the patients with adenocarcinomas and Crizotinib is an oral tyrosine kinase inhibitor (TKI), which has recently been approved for the treatment of NSCLC aberrantly expressing ALK.
- I reviewed the current development of molecular diagnosis of cancers, especially in the aspect for target therapies against lung cancer.

Histological type in NSCLC and the patterns of mutations in adenocarcinoma



*Summary of histotype classification in NSCLC according to the California Cancer Registry

**Kris MG, Johnson BE, Kwiatkowski DJ, et al. Identification of driver mutations in tumor specimens from 1,000 patients with lung adenocarcinoma: The NCI's Lung Cancer Mutation Consortium (LCMC). *J Clin Oncol* 29: 2011 (suppl; abstr CRA7506)

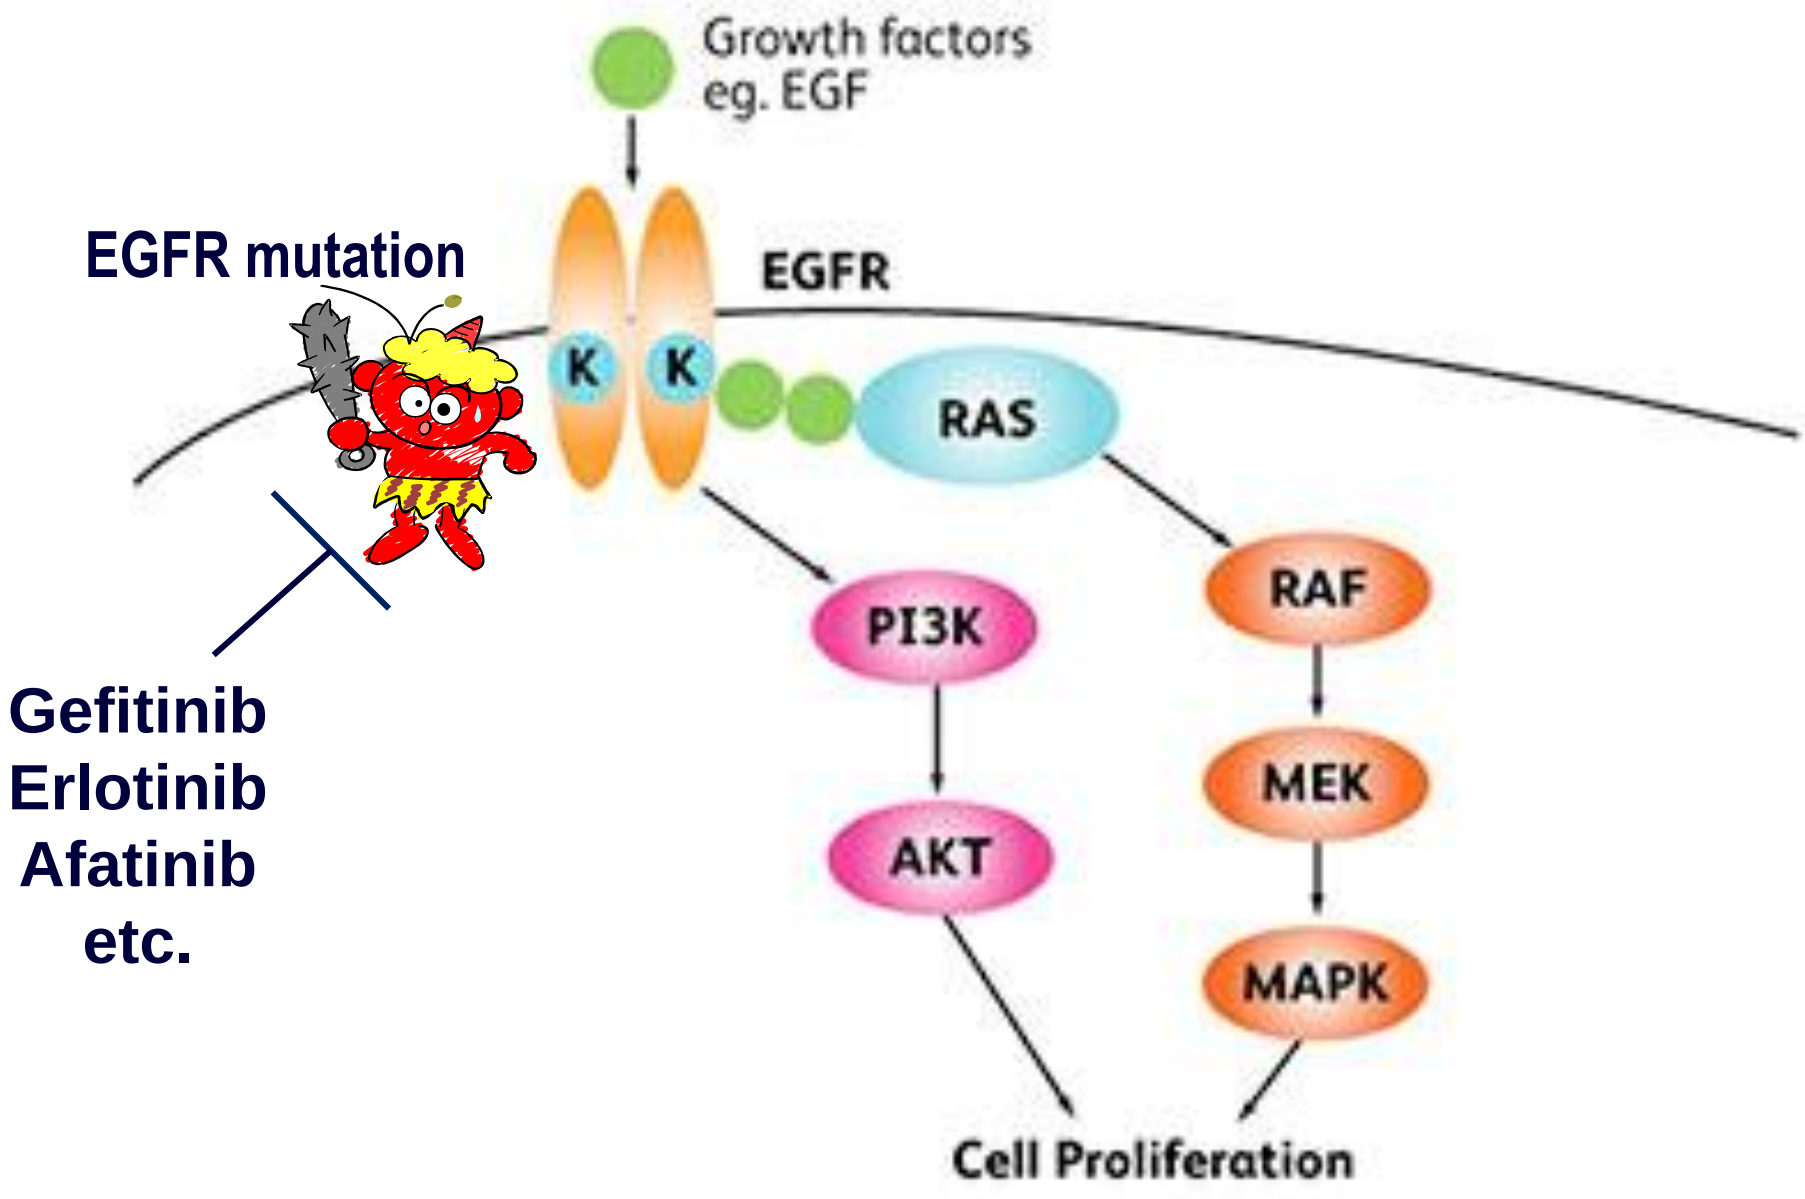
Oncogene Mutations Predict Likelihood of Resistance or Response to Targeted Therapies in Patients with NSCLC

Oncogene	Mutation Prevalence	Mutation-predicted Therapeutic Response	Predicted Overall Response Rates to Targeted Therapies
EGFR	Asians: 40% Caucasians: 10–15%	Sensitive to EGFR TKIs (most mutations)[a]	Erlotinib: ~82%–83%[4] Gefitinib: ~71%–73%[4]
KRAS	Asians: 10% Caucasians: 30%	Resistant to EGFR TKIs	0%–5%[2,5,7]
ALK	2–7%	Sensitive to ALK inhibitors	Crizotinib: 50%-61%[9,10]
		Resistant to EGFR TKIs	0%[b]

TKI, tyrosine kinase inhibitor.

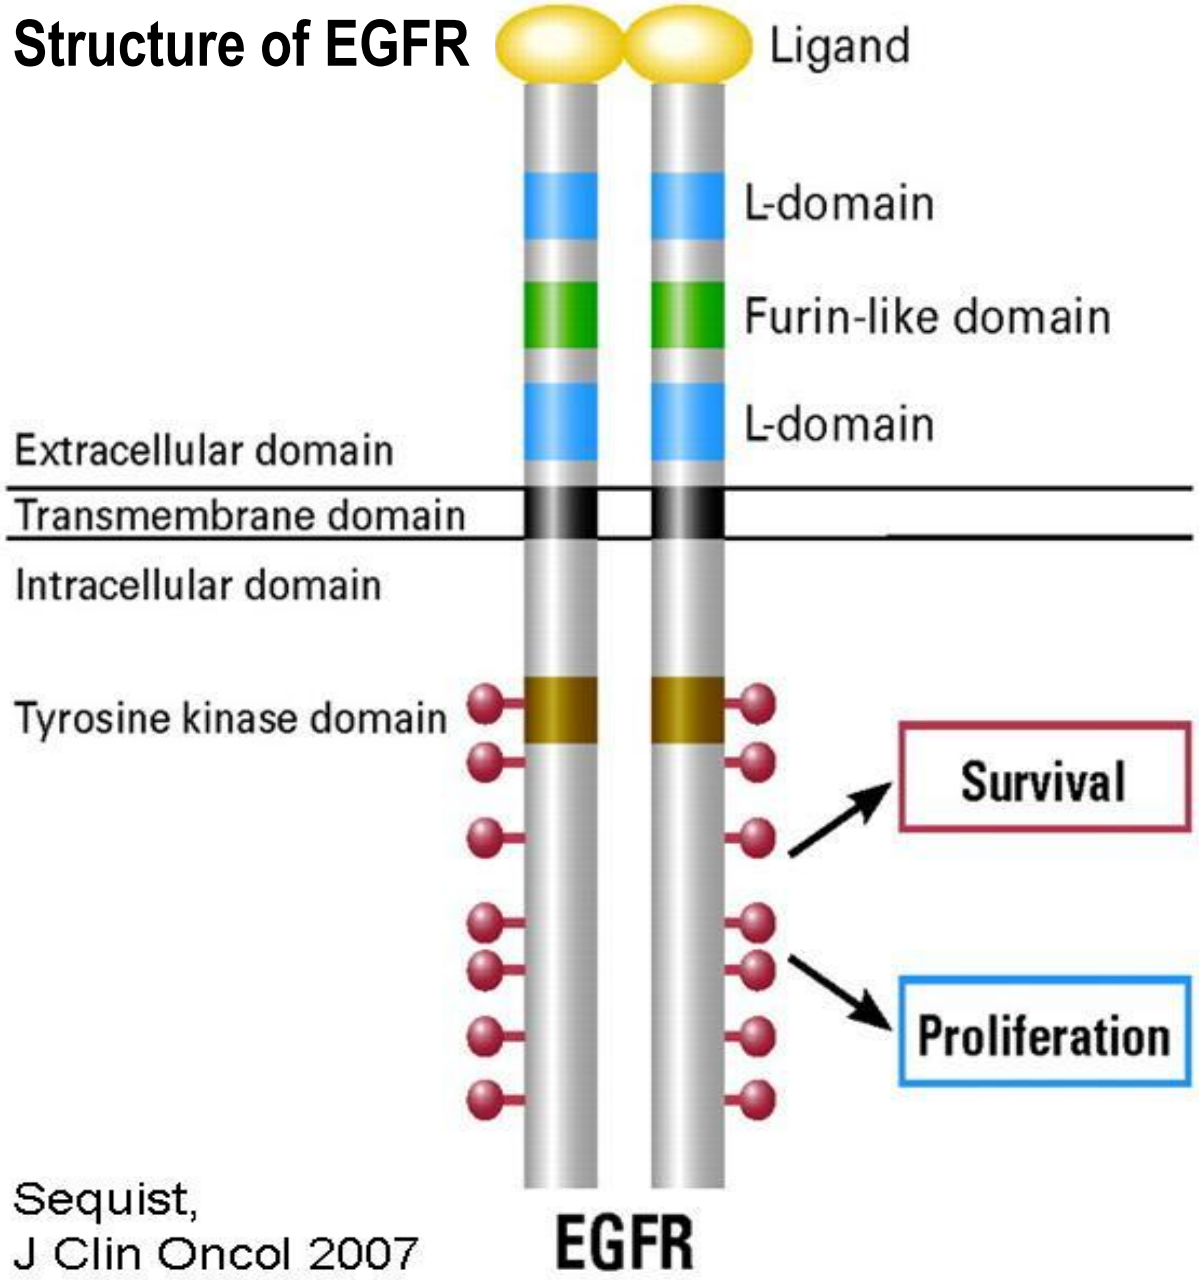
[a] Common mutations (exon 19 deletions and L858R) are associated with response to EGFR TKIs; other mutations such as T790M and exon 20 insertion are associated with decreased response or secondary resistance to TKIs.[4]

[b] Based on one study that included 10 patients positive for *EML4-ALK*.[8]



EGFR activating mutations in the tyrosine kinase domain lead to tumor growth. In such cases, molecular targeting therapy for EGFR is effective.

Structure of EGFR



Sequist,

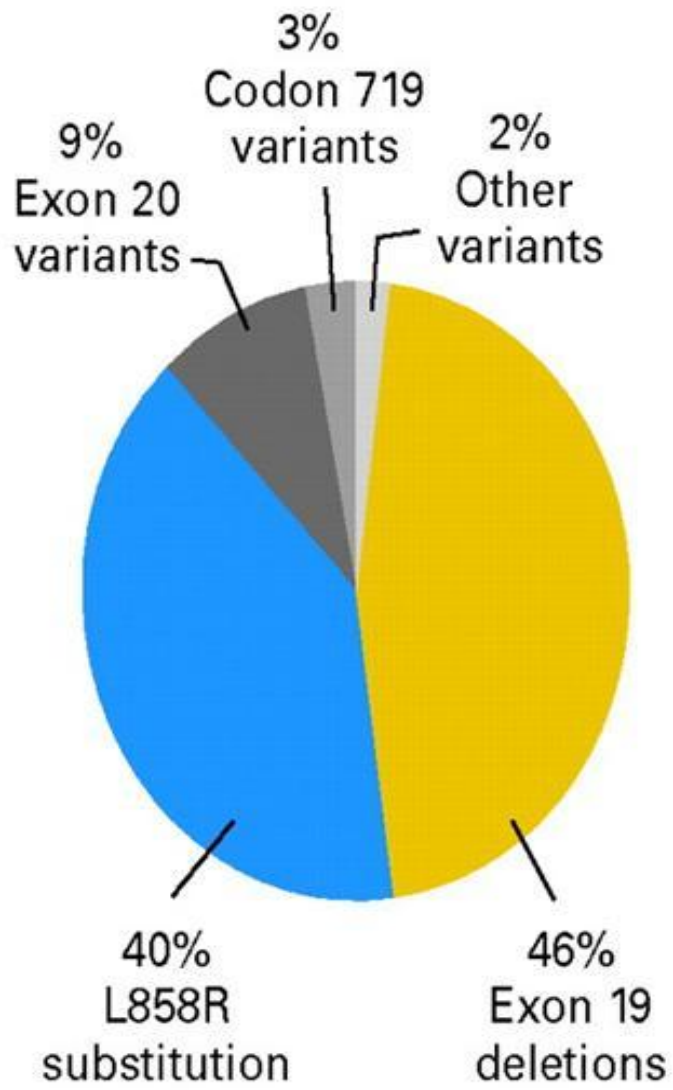
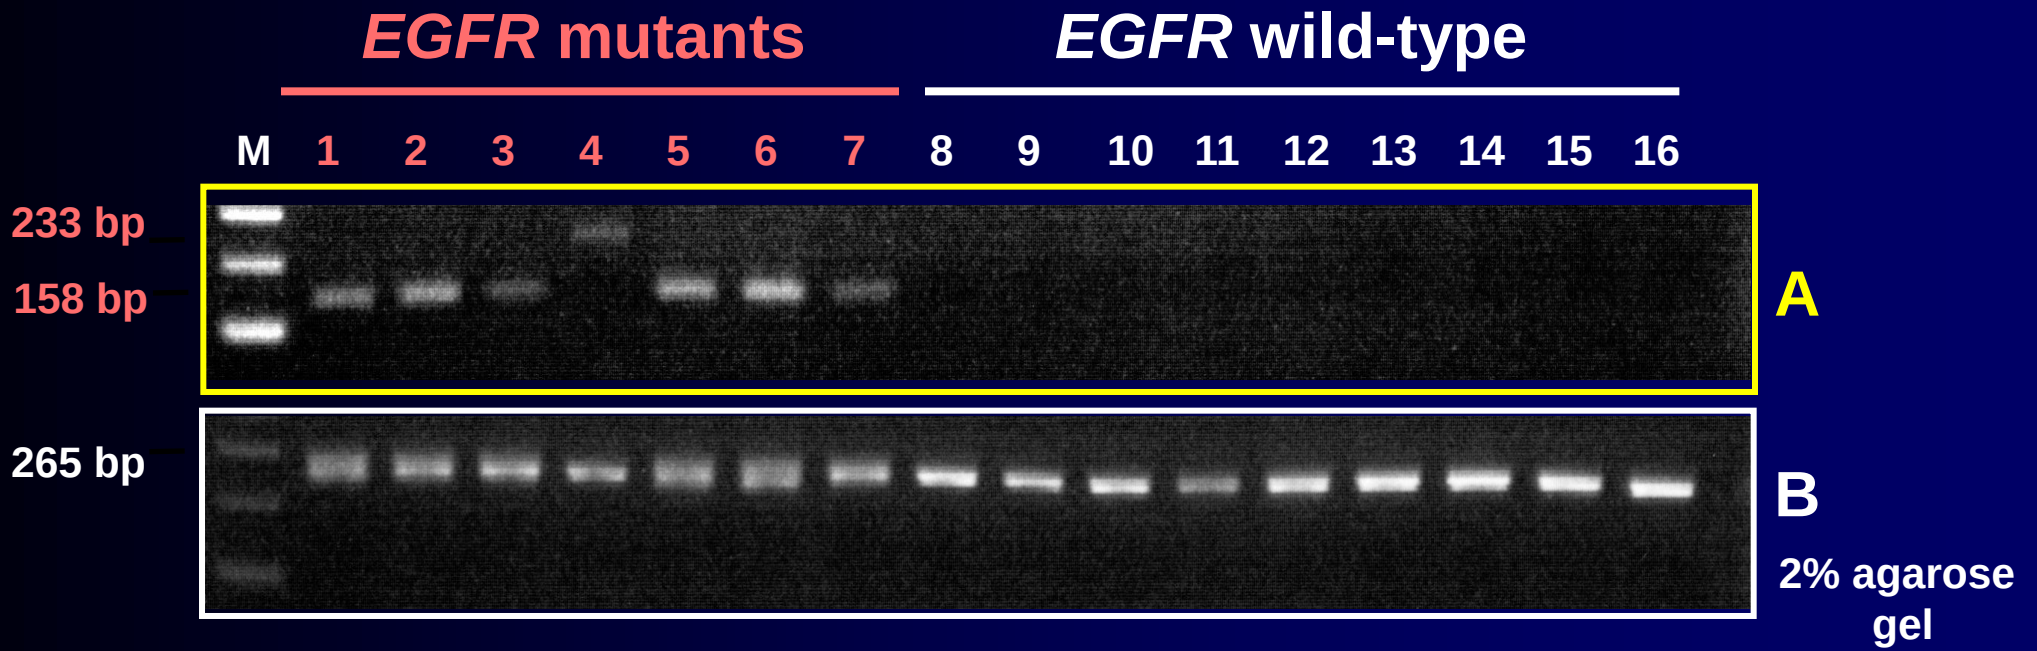
Mutations of EGFR



Detection of *EGFR* deletions (exon 19) and L858R (exon 21) by a single PCR (*Arifin et al., Research Signpost, 2009*)



A: mixture of EGFR mutation (deletions in exon 19 and L858R) specific primers

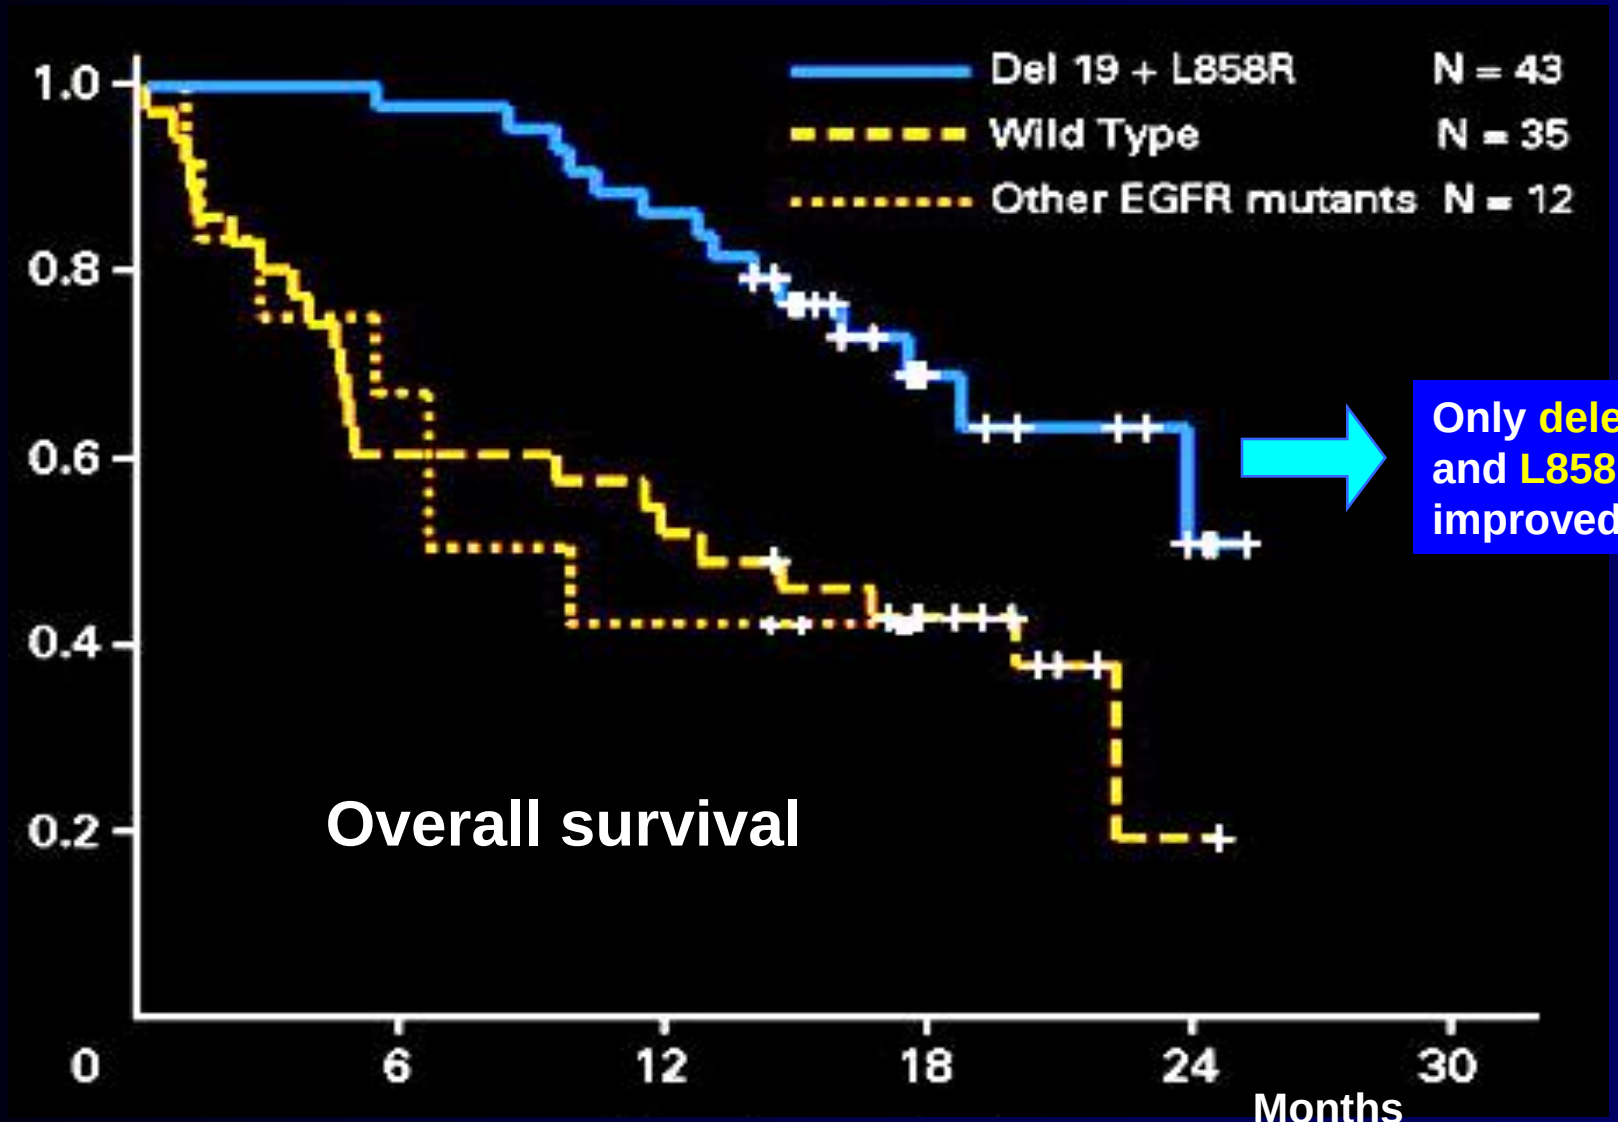
delE746-A750 (2235-2249: 1,2,6) , delE746-A750 (2236-2250: 5)

delL747-T751 (2239-2253: 3,7) , L858R (4)

B: common primer (control, not necessary for detection)

We could identify the cases with EGFR activating mutations.

EGFR mutation in NSCLC patients treated with first-line gefitinib monotherapy (*Yang et al., J Clin Oncol 26: 2745-53, 2008*)



Only deletion in exon 19 and L858R in exon 21 improved the prognosis

KRAS exists in the pathways downstream from EGFR. When *KRAS* mutations occur, EGFR inactivation cannot block this pathway. Thus, patients with *KRAS* mutations tend to be resistant to gefitinib and erlotinib.

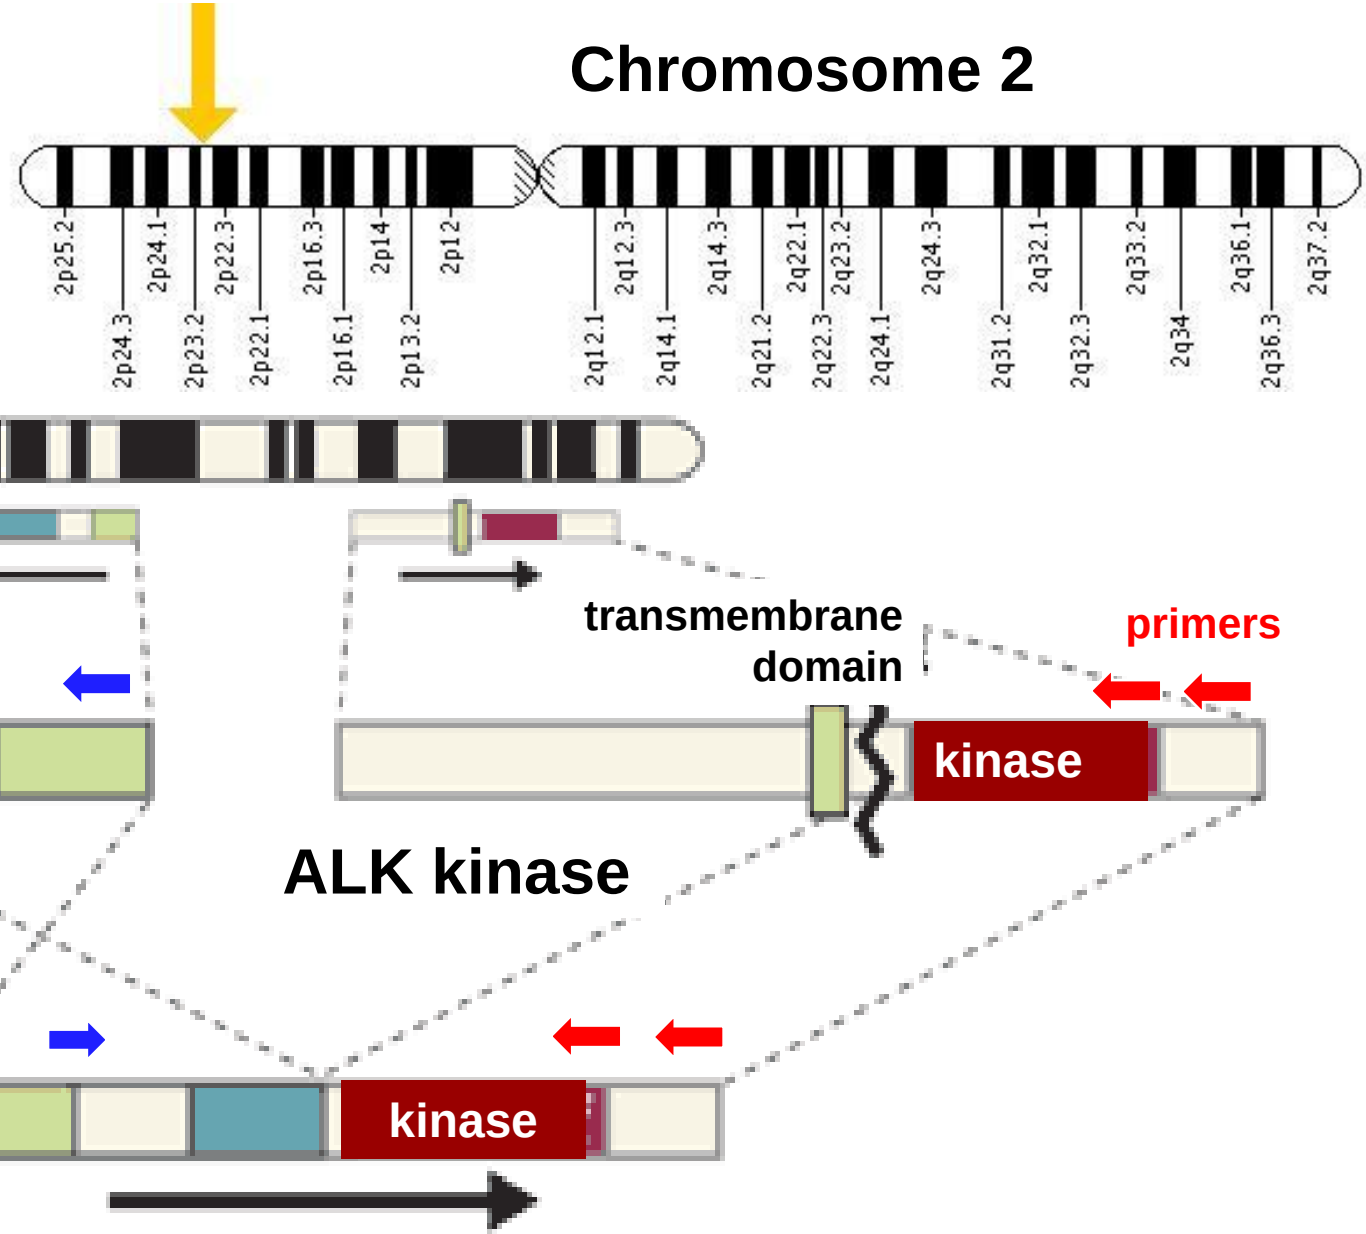
EML4-ALK fusion gene activates this pathway by Ras activation. In such cases, ALK inhibitors such as Crizotinib are effective.

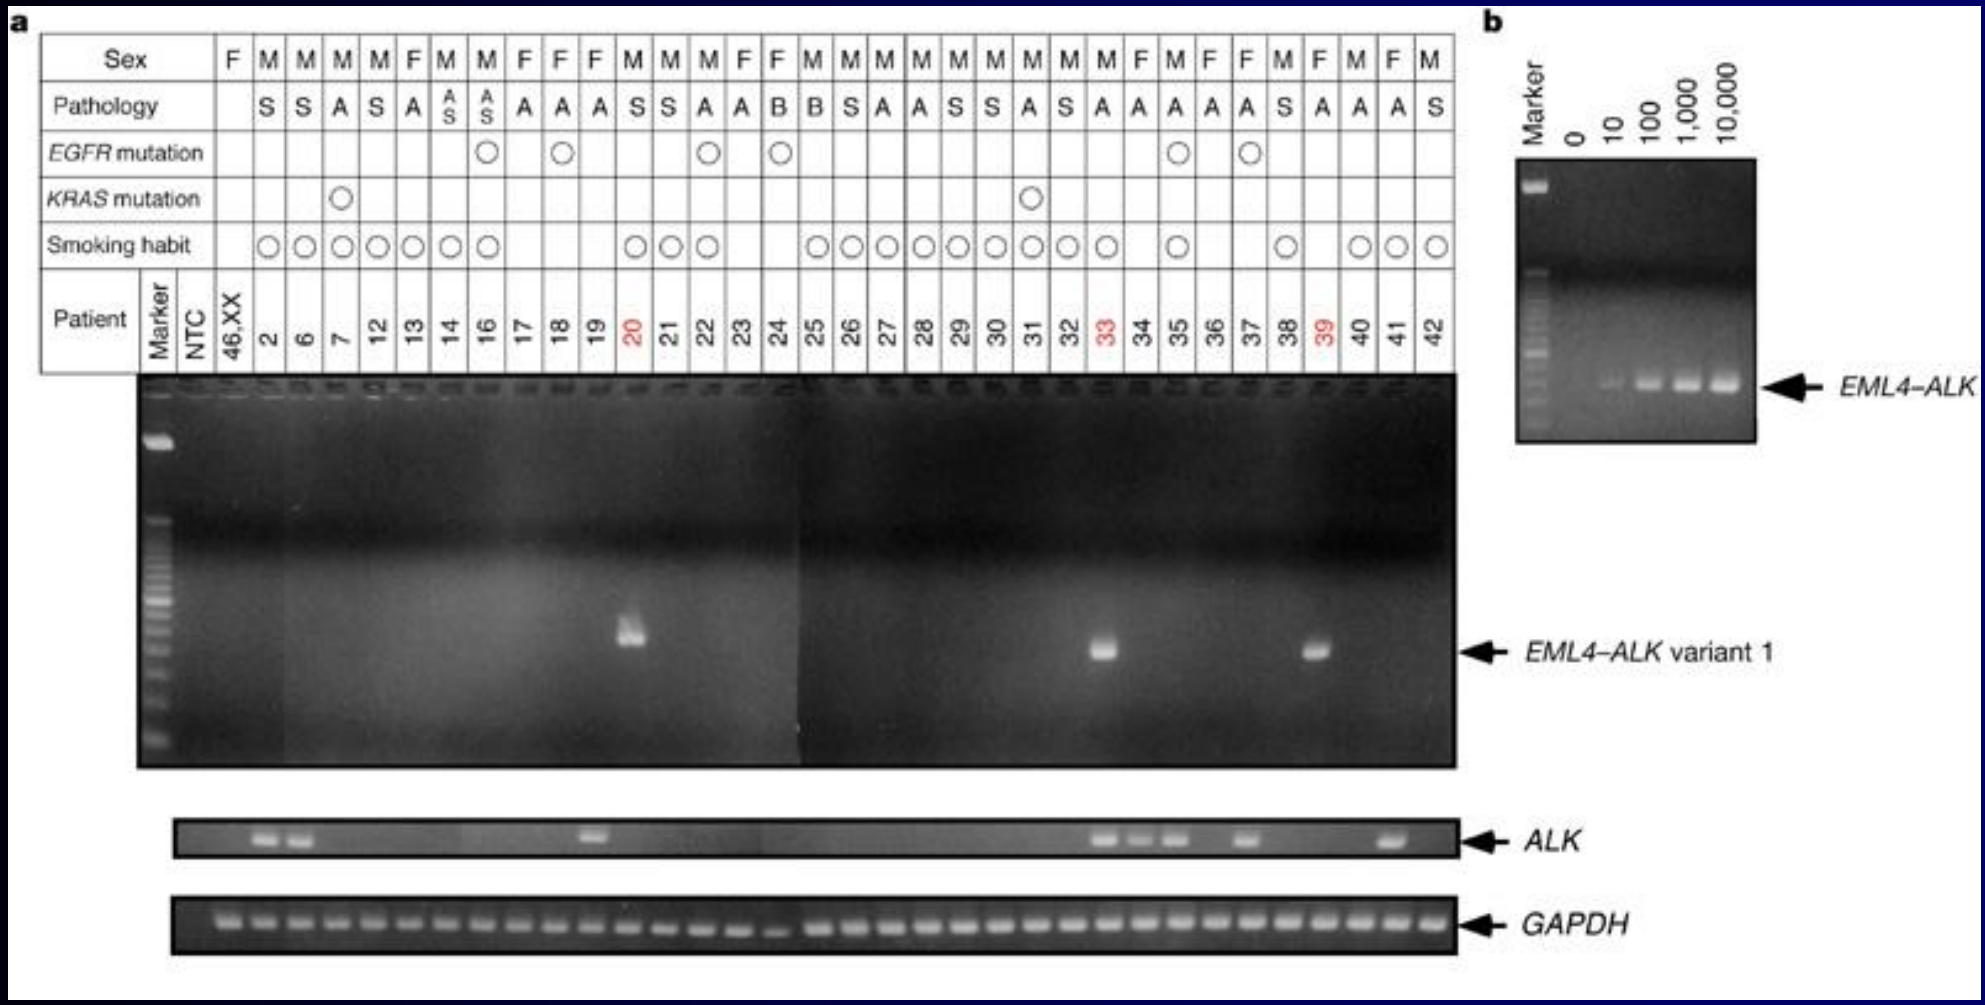
ALK aberrations: Lung cancer



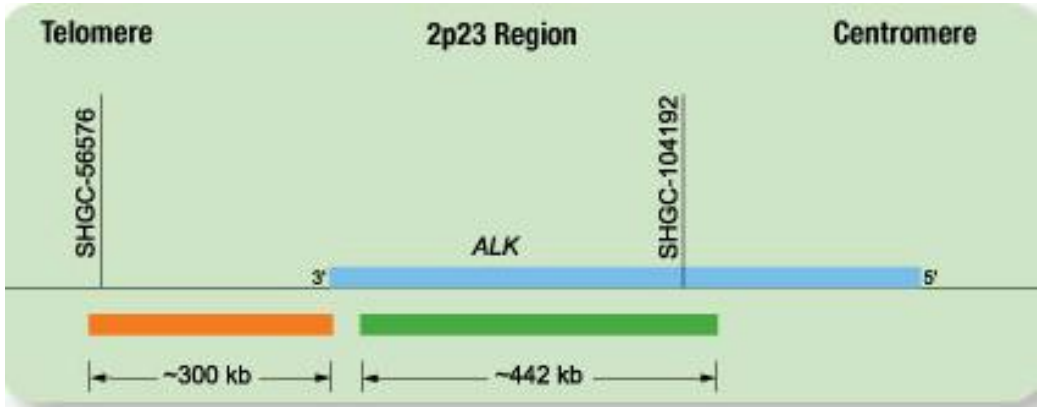
Activated EML4-ALK fusion kinase

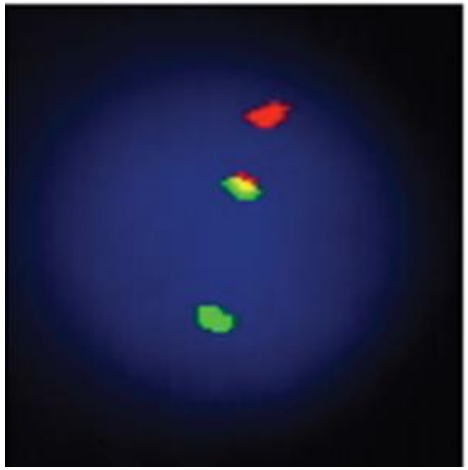
In lung cancer, ALK gene is translocated with inversed EML4 gene and activates fusion kinase. We designed the primes as shown in this slide and performed RT-PCR.

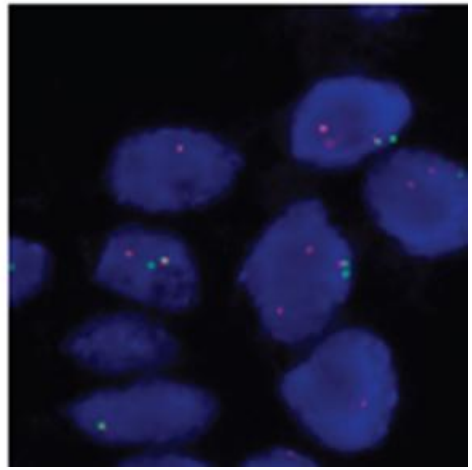
Detection of EML4-ALK fusion



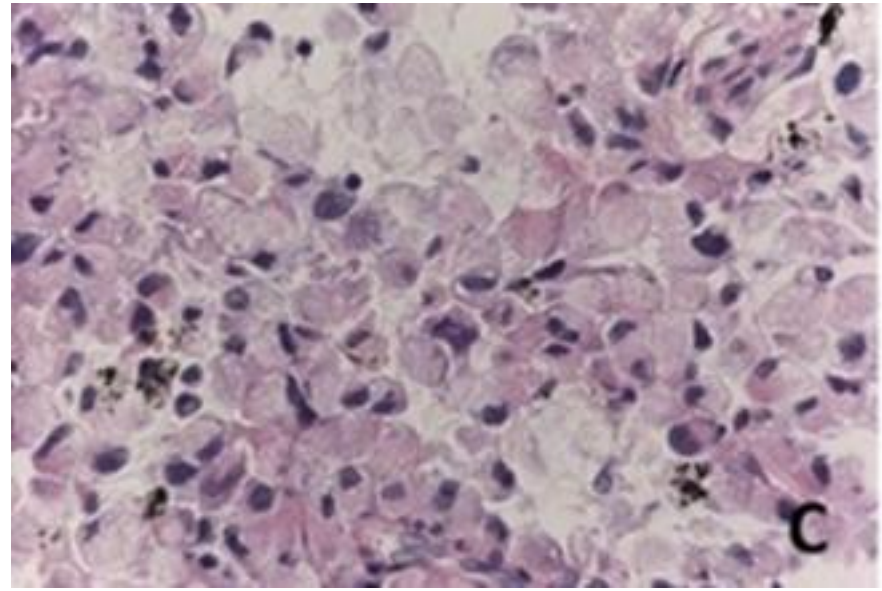
FISH for ALK fusion gene







IHC for ALK fusion gene

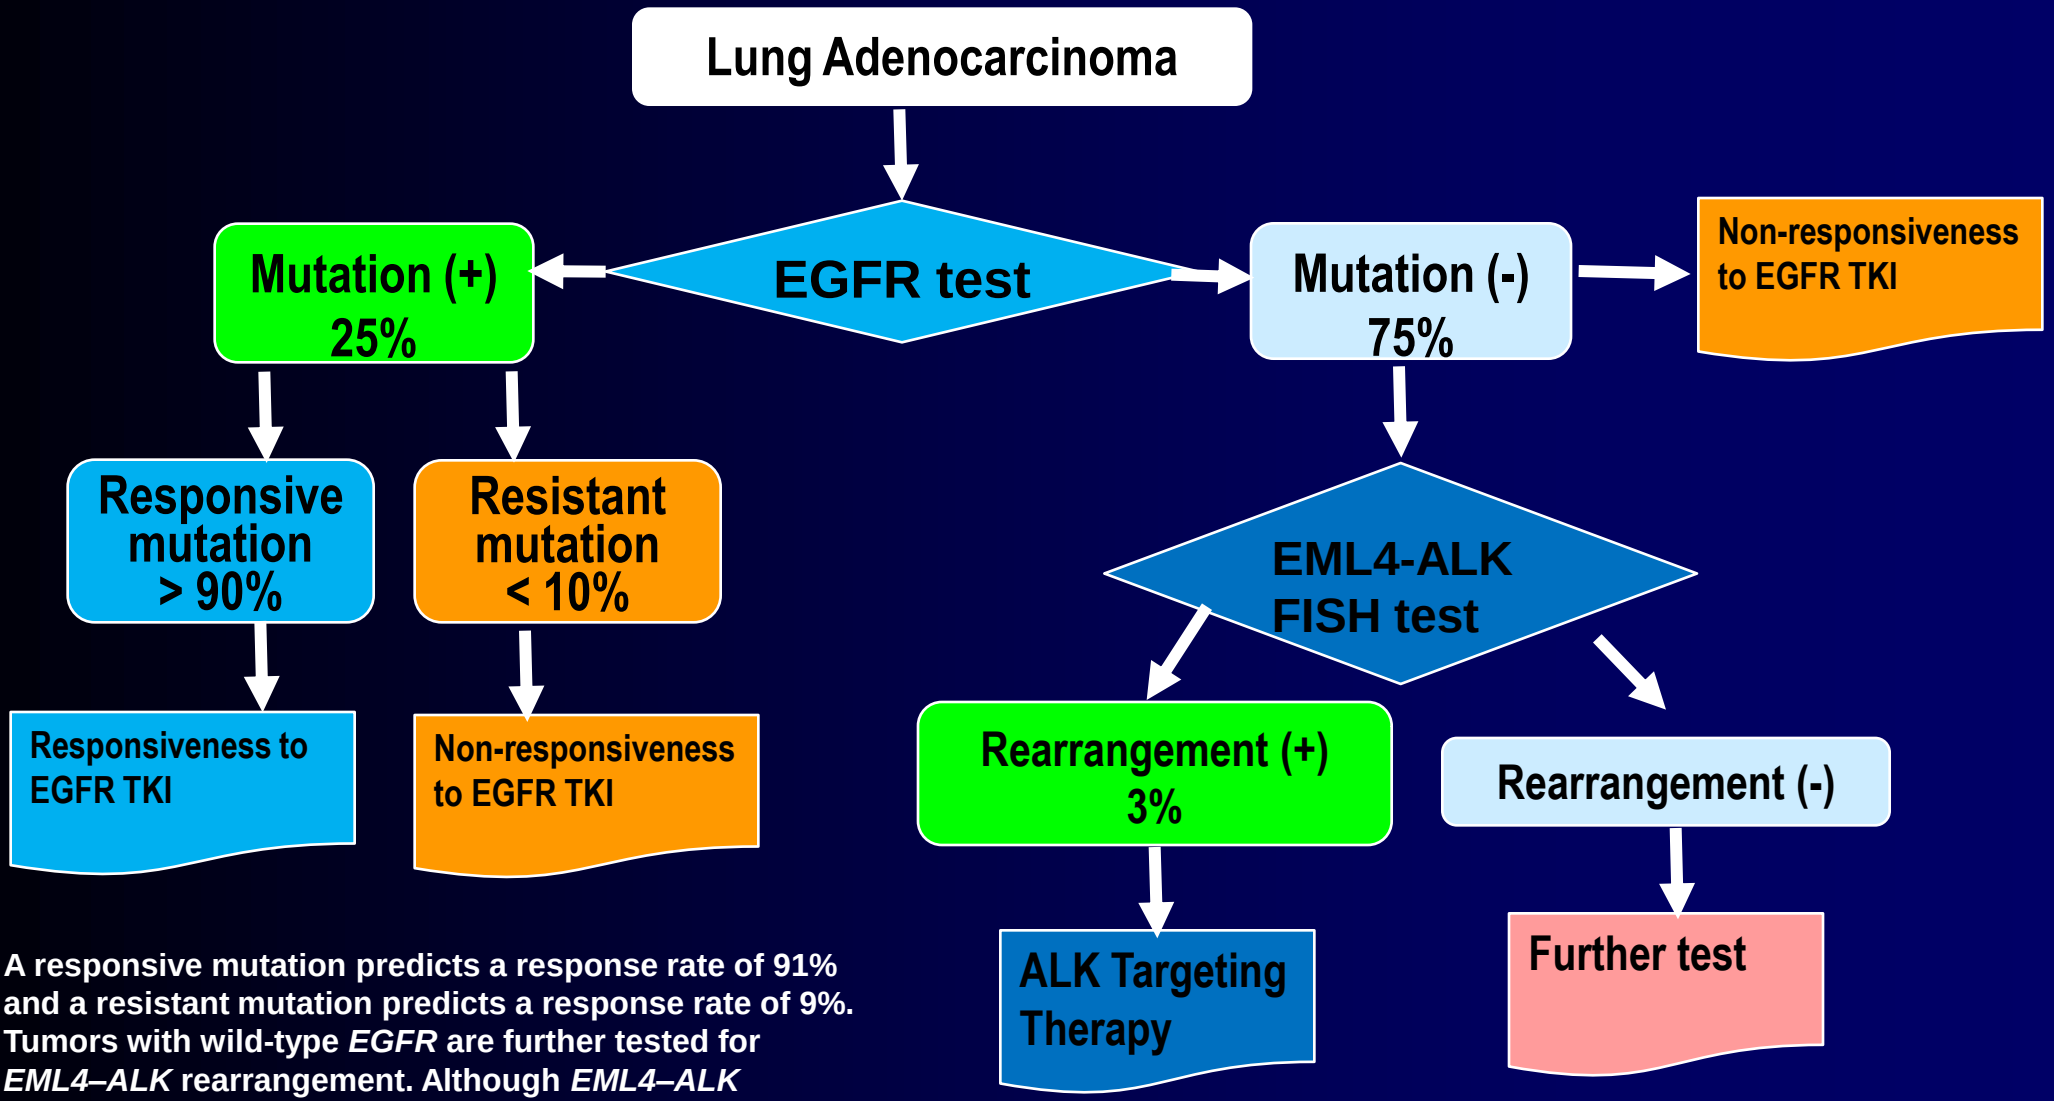


Detection methods for ALK fusion genes

	Pros	Cons
RT-PCR	Rapid, very sensitive and more accurate Very accurate	Need for high-quality RNA Not applicable for unknown partners Difficult to apply to archival tissues Difficult to confirm the presence of tumor cell
FISH	Applicable for any partners Screening methods for clinical trial Applicable to archival tissues	Expense Relative long turnaround time Less sensitive
IHC	Applicable for any partners Relative turnaround time Established in many labs Applicable to archival tissues Cheep	Indirect demonstration of the fusion gene Occasional false negative results Highly depends on antibody and detection method

Algorithm for molecular testing for patients with lung adenocarcinoma

in selecting patients who could benefit from *EGFR* and *EML4–ALKA* targeted therapy



A responsive mutation predicts a response rate of 91% and a resistant mutation predicts a response rate of 9%. Tumors with wild-type *EGFR* are further tested for *EML4–ALK* rearrangement. Although *EML4–ALK* rearrangement is found in only 3% of patients with lung adenocarcinoma, its presence predicts a 53% probability of response to targeted therapy.

a 53% probability of response to targeted therapy

Mutation type in Lung cancer genes

Figure 1 - Mutation types in lung cancer genome. Mutation types included three major types: substitution, deletion and insertion. Each of the major mutation types was categorized into frameshift mutation or in-frame mutation. The latter, although not causing a shift in the triplet reading frame, can, however, lead to the encoding of abnormal protein products.

Table 1. Lung cancer genetic aberrations and associated targeted therapy.

Biomarker gene	Aberration	Targeted therapeutic	Frequency of aberration [%]
EGFR	Mutation or amplification	Gefitinib, erlotinib, cetuximab	[10-25] (35% in Asian patients)
HER2 (ERBB2)	Mutation or amplification	Trastuzumab	[5-10]
BRAF	Mutation	Sorafenib	[2-3]
p53	Mutation or deletion	Advexin a p53 adenoviral vector	[30-50]
VEGF	Overexpression	Bevacizumab, afibercept	
PI3K	Modified and activated	BEZ235, LY294002	[1-3]
mTOR	Activated	Rapamycin, RAD001, CCL-779	[70-75]
RAS	Mutation leading to activation	Tipifarnib, lonafarnib	[10-15] (20-30% in Adenocarcinoma)
MEK	Activated	Trametinib, salumetinib	[1-2]
c-KIT	Overexpressed	Imatinib	[1-2]
EML/ALK	Fusion	Crizotinib	[5-13]

Summary

- In non-small cell lung cancer (NSCLC) patients, molecular diagnosis including epidermal growth factor receptor (EGFR) gene mutations and EML4-ALK fusion is necessary to choose targeting therapy.
- Next generation sequencing (NGS) is a powerful procedure to identify molecular targets in NSCLC .
